7.4 Control of Gene Expression in Prokaryotes. An organism's DNA encodes all of the RNA and protein molecules required to construct its cells. Yet organisms are able to differentially express their genes to make cell-specific products necessary for cellular development at specific times. Gene expression is the process through which the cell translates the genetic code into amino acids for protein production. Unlike in eukaryotes, the two main stages, which are transcription and translation, can happen at the same time in prokaryotes. During transcription, the cell translates DNA into a messenger RNA (mRNA) molecule.

Gene Regulation in Prokaryotes: In bacteria the expression of genes is controlled by extracellular

signals often present in the medium in which bacteria are grown. These signals are carried to the genes by regulatory proteins. Regulatory proteins are of two types.

Prokaryotic Gene expression Steps. The products of the lacZ and LacY genes are encoded in a single polycistronic mRNA molecule. (The product of lacA gene is an enzyme (transacetylase) used in the metabolism of certain  $\beta$ -galactosides other than lactose. The positive and negative regulation of the lac operon is explaining below.

How do prokaryotes use operons to control gene expression? Why? Houses usually have a light source in every room, but it would be a waste of energy to leave every light on all the time, so there are switches to turn off the lights in rooms that are not in use. Sometimes one switch controls several lights in the same room. Likewise, prokaryotic cells can turn genes on and off based on
