In queueing theory, a discipline within the mathematical theory of probability, an M/M/1 queue represents the queue length in a system having a single server, where arrivals are determined by a Poisson process and job service times have an exponential distribution.The model name is written in Kendall's notation.The model is the most elementary of queueing models and an attractive object of ...

A Markov chain is a random process described by states and the transitions between those states. Transitions between states are probabilistic and exhibit a property called memorylessness. The memorylessness property ensures that the probability distribution for the next state depends only on the current state.

If the service rate is less than the arrival rate, the chain is transient and the length of the queue grows to infinity. If the service rate is greater than the arrival rate, the chain is positive recurrent. At the boundary between these two cases, when the arrival and service rates are the same, the chain is null recurrent.

So when the equivalent conditions are satisfied, the Markov chain $\bs X = \{X_t: t \in [0, \infty)\}$ is also said to be uniform. As we will see in a later section, a uniform, continuous-time Markov chain can be constructed from a discrete-time Markov chain and an independent Poisson process.

A Markov chain is a stochastic model describing a sequence of possible events in which the probability of each event depends only on the state attained in the previous event. A countably

infinite sequence, in which the chain moves state at discrete time steps, gives a discrete-time Markov chain (DTMC). A continuous-time process is called a continuous-time Markov chain (CTMC).
